Python Keywords

Keywords are the reserved words in python

We can't use a keyword as variable name, function name or any other identifier

✓ Keywords are case sensitive

In [3]: #Get all keywords in python 3.6

```
import keyword

print(keyword.kwlist)

print("\nTotal number of keywords: ", len(keyword.kwlist))
```

```
['False', 'None', 'True', 'and', 'as', 'assert', 'break', 'class', 'continue', 'def', 'del', 'elif', 'else', 'except', 'finally', 'for', 'from', 'global', 'if', 'import', 'in', 'is', 'lambda', 'nonlocal', 'not', 'or', 'pass', 'raise', 'return', 'try', 'while', 'with', 'yield']
```

Identifiers

Identifier is the name given to entities like class, functions, variables etc. in Python. It helps differentiating one entity from another.

Rules for Writing Identifiers:

1. Identifiers can be a combination of letters in lowercase (a to z) or uppercase (A to Z) or digits (0 to 9) or an underscore (_).
2. An identifier cannot start with a digit. 1variable is invalid, but variable1 is perfectly fine.
3. Keywords cannot be used as identifiers.

In [6]:

```
abc_12 = 12; ✓  
global = 1
```

```
File "<ipython-input-6-461be8cb845a>", line 2  
    global = 1  
          ^
```

SyntaxError: invalid syntax

Python Comments

Comments are lines that exist in computer programs that are ignored by compilers and interpreters.

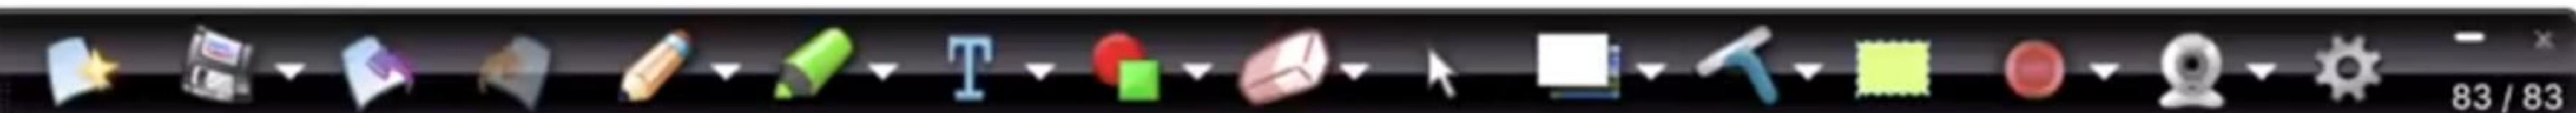

Including comments in programs makes code more readable for humans as it provides some information or explanation about what each part of a program is doing.

In general, it is a good idea to write comments while you are writing or updating a program as it is easy to forget your thought process later on, and comments written later may be less useful in the long term.

In Python, we use the hash (#) symbol to start writing a comment.

```
In [1]: #Print Hello, world to console  
        print("Hello, world")
```

Hello, world

File Edit View Insert Cell Kernel Help

Python 3 0

Multi Line Comments

we have comments that extend multiple lines, one way of doing it is to use hash (#) in the beginning of each line.

```
n [2]: #This is a long comment  
#and it extends  
#Multiple lines
```

Another way of doing this is to use triple quotes, either """ or """.

```
n [3]: """This is also a  
perfect example of  
multi-line comments"""
```

```
ut[3]: 'This is also a\nperfect example of\nmulti-line comments
```

Python Indentation

1. Most of the programming languages like C, C++, Java use braces {} to define a block of code.
Python uses indentation.
2. A code block (body of a function, loop etc.) starts with indentation and ends with the first unindented line. The amount of indentation is up to you, but it must be consistent throughout that block.
3. Generally four whitespaces are used for indentation and is preferred over tabs.

```
In [14]: for i in range(10): # we will look at for loop in detail later.  
|   print(i)
```

```
0  
1  
2  
3  
4  
5  
6  
7  
8
```

Python Statement

Instructions that a Python interpreter can execute are called statements.

Examples:

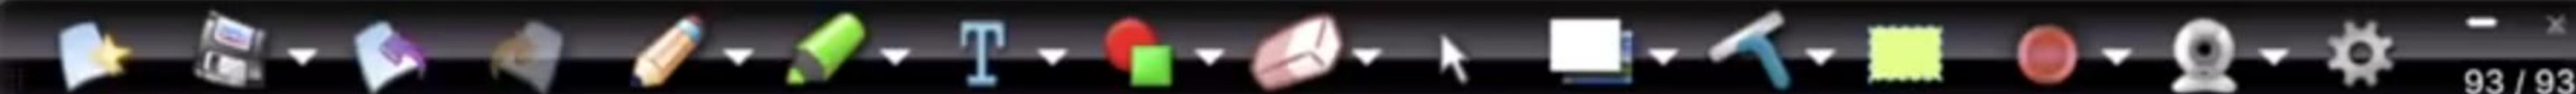

In [17]: `a = 1 #single statement`

Multi-Line Statement

In Python, end of a statement is marked by a newline character. But we can make a statement extend over multiple lines with the line continuation character () .

In [18]: `a = 1 + 2 + 3 + \n 4 + 5 + 6 + \n 7 + 8`

Variables

A variable is a location in memory used to store some data (value).

They are given unique names to differentiate between different memory locations. The rules for writing a variable name is same as the rules for writing identifiers in Python.

We don't need to declare a variable before using it. In Python, we simply assign a value to a variable and it will exist. We don't even have to declare the type of the variable. This is handled internally according to the type of value we assign to the variable.

Variable Assignments

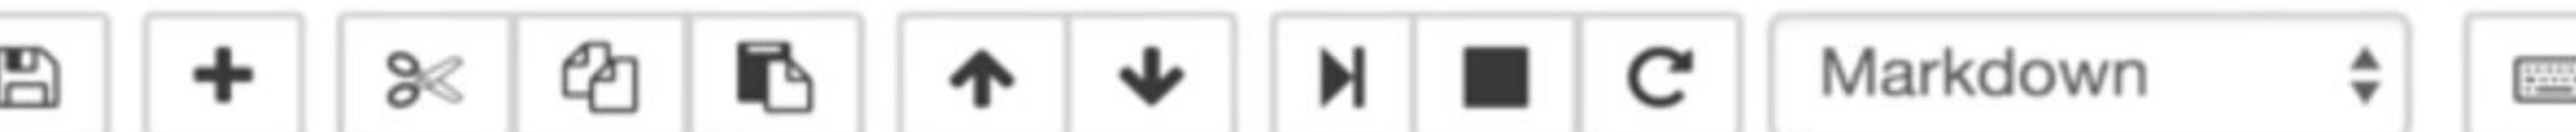

In [1]: *#We use the assignment operator (=) to assign values to a variable*

```
a = 10  
b = 5.5

Data Types

Every value in Python has a datatype. Since everything is an object in Python programming, data types are actually classes and variables are instance (object) of these classes.

Numbers

Integers, floating point numbers and complex numbers falls under Python numbers category. They are defined as int, float and complex class in Python.

We can use the type() function to know which class a variable or a value belongs to and the isinstance() function to check if an object belongs to a particular class.

```
In [7]: a = 5 #data type is implicitly set to integer
      print(a, " is of type", type(a))

      5  is of type <class 'int'>
```

```

Python List

List is an ordered sequence of items. It is one of the most used datatype in Python and is very flexible. All the items in a list do not need to be of the same type.

Declaring a list is , Items separated by commas are enclosed within brackets [].

```
In [52]: a = [10, 20.5, "Hello"]
          print(a[2])           #print 1st index element
```

Hello

Lists are mutable, meaning, value of elements of a list can be altered.

```
In [15]: a[1] = 30.7
          print(a)
```

[10, 30.7, 'Hello']

Python Tuple

Operators

Operators are special symbols in Python that carry out arithmetic or logical computation. The value that the operator operates on is called the operand.

Operator Types

1. Arithmetic operators
2. Comparison (Relational) operators
3. Logical (Boolean) operators
4. Bitwise operators
5. Assignment operators
6. Special operators

Example:

In [27]: `x, y = 10, 20`

```
#addition  
print(15%2)  
  
#subtraction(-)  
  
#multiplication(*)  
  
#division(/)  
  
#modulo division (%)  
  
#Floor Division (//)  
  
#Exponent (**)
```

$$\begin{array}{r} 2) \overline{) 15 } (1 \\ \underline{14} \\ 1 \end{array}$$

$\textcircled{1} = 15 \% 2$

Assignment operators

Assignment operators are used in Python to assign values to variables.

`a = 5` is a simple assignment operator that assigns the value 5 on the right to the variable `a` on the left.

=, +=, -=, *=, /=, %=, //=, **=, &=, |=, ^=, >>=, <<= are Assignment operators

```
In [14]: a = 10  
  
a += 10          #add AND  
print(a)  
  
#subtract AND (--)  
  
#Multiply AND (*=)
```

Special Operators

Identity Operators

is and **is not** are the identity operators in Python.

They are used to check if two values (or variables) are located on the same part of the memory.

```
In [15]: a = 5  
        b = 5  
        print(a is b)      #5 is object created once both a and b points to same object
```

a → 5
b → 5

True

```
In [16]: ll = [1, 2, 3]
          12 = [1, 2, 3]
          print(ll is 12)
```

File Edit View Insert Cell Kernel Help

Trusted

Python 3

```
In [15]: a = 5  
b = 5  
print(a is b)      #5 is object created once both a and b points to same object  
  
#check is not
```

True

```
In [16]: l1 = [1, 2, 3]  
l2 = [1, 2, 3]  
print(l1 is l2)
```

False

```
In [35]: s1 = "AAIC"  
s2 = "AAIC"  
print(s1 is s2)
```

True

MemberShip Operators

Python 3

Markdown

MemberShip Operators

in and **not in** are the membership operators in Python.

They are used to test whether a value or variable is found in a sequence (string, list, tuple, set and dictionary).

```
In [19]: lst = [1, 2, 3, 4]
print(1 in lst)      #check 1 is present in a given list or not

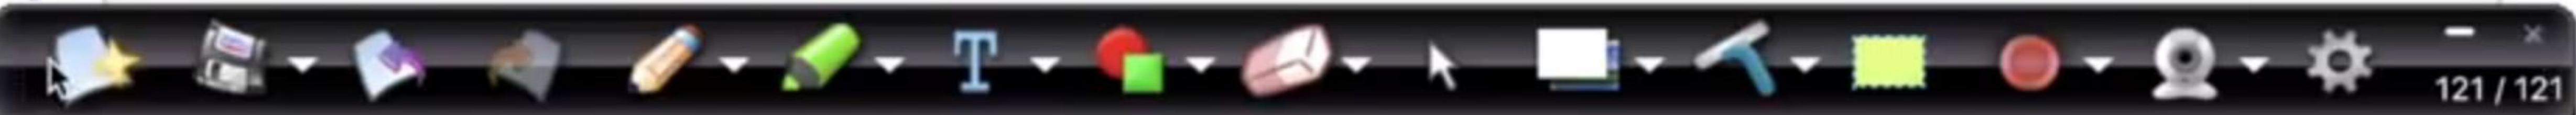

#check 5 is present in a given list
```

True

```
In [20]: d = {1: "a", 2: "b"} # this is a dictionary
print(1 in d)
```

True

```
In [ ]:

Python if ... else Statement

The **if...elif...else** statement is used in Python for decision making.

if statement syntax

The program evaluates the test expression and will execute statement(s) only if the text expression is True.

If the text expression is False, the statement(s) is not executed.

Flow-Control/1_if-else/ x if-elif-else x Chekuri Srikan...

Example

In [5]:

```
num = 10
# test-condition
# try 0, -1 and None
if num > 10:
    print("Number is positive")
    print("This will print always")      #This print statement always prints
#change number
```

This will print always

if ... else Statement

Syntax:

Flow-Control/1_if-else/ if-elif-else

C localhost:8888/notebooks/Google%20Drive/OnlineVideos/2/python-basics/Flow-Control/1_if-else/if-elif-else.ipynb

File Edit View Insert Cell Kernel Help Trusted Python 3

Example

```
In [6]: num = 10
if num > 0:
    print("Positive number")
else:
    print("Negative Number")
```

Positive number

if...elif...else Statement

Syntax:

if test expression:

Flow-Control/1_if-else/ if-elif-else

C localhost:8888/notebooks/Google%20Drive/OnlineVideos/2/python-basics/Flow-Control/1_if-else/if-elif-else.ipynb

File Edit View Insert Cell Kernel Help Trusted Python 3

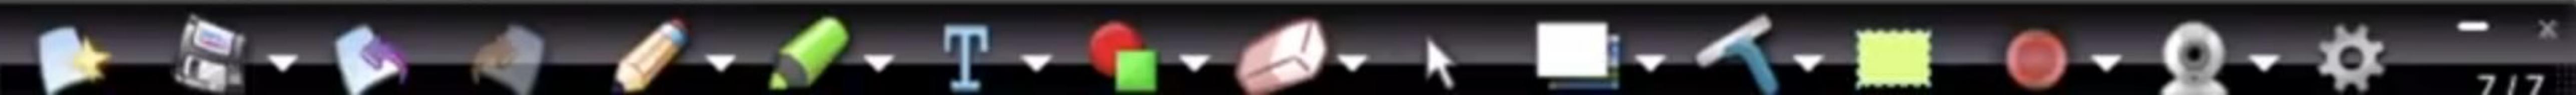

Example:

```
In [15]: num = 0
if num > 0:
    print("Positive number")
elif num == 0:
    print("ZERO")
else:
    print("Negative Number")
ZERO
```

else if

Nested if Statements

We can have a if...elif...else statement inside another if...elif...else statement. This is called nesting in computer programming.

Flow-Control/1_if-else/ if-elif-else

Python while loop

The while loop in Python is used to iterate over a block of code as long as the test expression (condition) is true.

Syntax:

```
while test_expression:  
    Body of while
```

The body of the loop is entered only if the test_expression evaluates to True.

After one iteration, the test expression is checked again.

This process continues until the test expression evaluates to False.

In [1]: #Find product of all numbers present in a list

```
lst = [10, 20, 30, 40, 50]
product = 1
index = 0
while index < len(lst):
    product *= lst[index]
    index += 1
print("Product is: {}".format(product))
```

Product is: 12000000

Handwritten annotations:

- Annotations on the list: '10' has a circled '1' above it, '20' has a circled '2' above it, '30' has a circled '3' above it, and '50' has a circled '4' above it.
- Annotations on the while loop condition: 'index < len(lst)' is circled and labeled 'test cond'.
- Annotations on the loop body:
 - 'product *= lst[index]' is circled.
 - 'index += 1' is circled.
- Annotations on the final value:
 - '0 < 5 ✓' is written next to the condition.
 - 'product = 10' is written below the first iteration.
 - 'index = 1' is written below the first iteration.
 - '1 < 5' is written next to the condition for the second iteration.
 - 'product = 200' is written below the second iteration.
 - 'index = 2' is written below the second iteration.

while Loop with else

File Edit View Insert Cell Kernel Help

Trusted

| Python 3 O

Markdown

The else part is executed if the condition in the while loop evaluates to False. The while loop can be terminated with a break statement.

In such case, the else part is ignored. Hence, a while loop's else part runs if no break occurs and the condition is false.

```
In [2]: numbers = [1, 2, 3]

#iterating over the list
index = 0
✓while index < len(numbers):
    print(numbers[index])
    index += 1
✓else:
    print("no item left in the list")
    1
    2
    3
    no item left in the list
```

In [1]: #Find product of all numbers present in a list

```
✓ lst = [10, 20, 30, 40, 50]
✓ product = 1
#iterating over the list
for ele in lst:
    product *= ele
print("Product is: {}".format(product))
```

Handwritten annotations:

- A vertical orange checkmark is placed next to the first line of code.
- The list elements [10, 20, 30, 40, 50] are circled in orange, with arrows pointing from the word "lst" in the code to each circled element.
- The variable "product" is circled in orange, with an arrow pointing from the assignment statement "product = 1" to it.
- The loop control "for ele in lst:" is circled in orange, with an arrow pointing from the "ele" in "for ele in lst:" to the "ele" in "product *= ele".
- The assignment "product *= ele" is circled in orange, with an arrow pointing from the "product" in "product *= ele" to the "product" in "product = 1".
- Handwritten text "ele = 10 | ele = 30 | ele = 50" is written vertically next to the list elements.
- Handwritten text "ele = 20 | ele = 40" is written vertically below the first two elements.
- Handwritten text "product = product * ele" is written below the assignment line.
- Handwritten text "ele = 10 | ele = 30 | ele = 50" is written vertically next to the list elements.
- Handwritten text "ele = 20 | ele = 40" is written vertically below the first two elements.
- Handwritten text "product = product * ele" is written below the assignment line.

range() function

We can generate a sequence of numbers using range() function. range(10) will generate numbers from 0 to 9 (10 numbers).

File Edit View Insert Cell Kernel Help

Trusted

Python 3

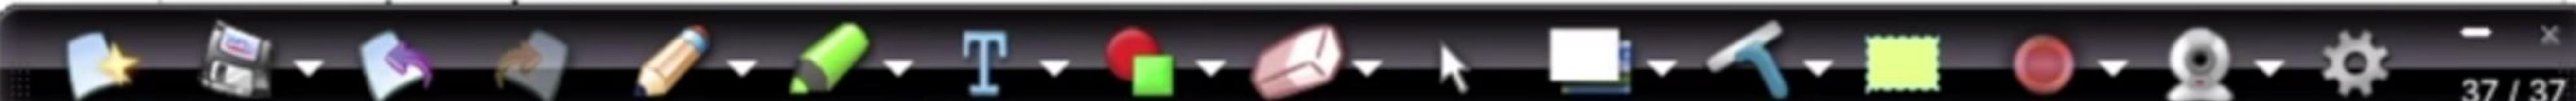

This function does not store all the values in memory, it would be inefficient. So it remembers the start, stop, step size and generates the next number on the go.
